

Spot The Difference

Ladybirds are an insect and they even eat other insects. One ladybird might live for less than year but in that time might eat as many as 5000 other insects! As with all insects, ladybirds should have six legs. But the number of spots changes between different ladybird species. The picture below shows two populations of ladybirds seen in the bottom of two separate containers. There are ten differences between the two populations, can you find them all?
